

Environmental effects on galaxy evolution in the distant Universe

Francesco Valentino

Advisor: Dr. Emanuele Daddi

Journées des thésards, Saclay, July 1st 2015

All you want to know about me

First name, family name: **Francesco Valentino**

All you want to know about me

Cursus: Bachelor and Master's degree in
Astronomy at **Università di Padova**

All you want to know about me

How did CEA happen? Through collaboration
with scientists in Padova

Galaxy ethology

From the Merriam-Webster:

Nature: *the way that a person or animal behaves : **the character or personality** of a person or animal*

Nurture: *The sum of the **environmental factors** influencing the behavior and traits expressed by an organism*

Galaxy ethology

This thesis:

Nature: *the way that a **galaxy** behaves:
internal properties of a galaxy*

Nurture: *The sum of the **environmental factors** influencing the behavior and traits expressed by **a galaxy***

Density

Galaxy morphologies, colors, luminosities, star formation rates, masses, sizes(?) change with the environment **in the local Universe.**

Galaxy environment

Galaxy morphologies, colors, luminosities, star formation rates, masses, sizes(?) change with the environment **in the local Universe.**

Is this true in the younger, far-away Universe?

When did this process started?

How did it happen?

How do far-away dense environments look like? What do we know about them?

[...]

A far-away cluster

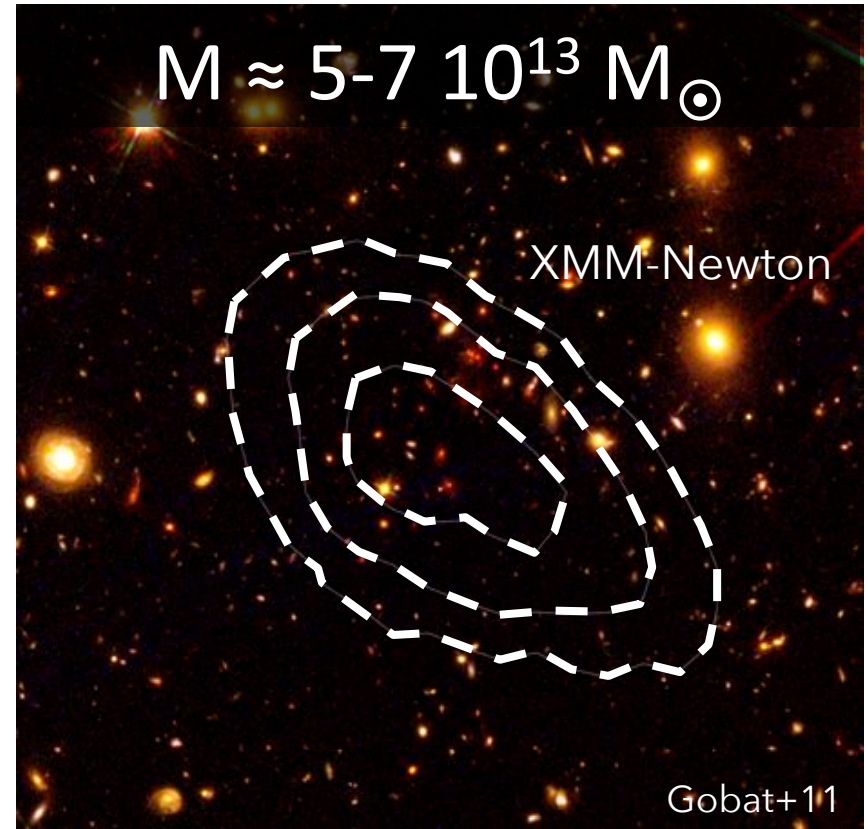

Redshift $z = 1.99 \rightarrow 10.4$ Gyr ago

A far-away cluster

A **relatively evolved cluster** that hosts a **significant fraction of active galaxies** (Gobat+2011, 2013, Strazzullo+2013).

Extensively followed-up:

- **Imaging** in 13 bands
- **Spectroscopy** of star-forming galaxies to study the properties of ionized gas

A far-away cluster

Numbers:

3: Subaru/MOIRCS nights (April 2013)

7.5: total hours of usable integration time per mask on the cluster (2 masks)

10: Observed cluster star-forming galaxies

78(%): success rate in detecting $H\alpha$ ($>3\sigma$ significance)

6(%): success rate in detecting $[NII] \lambda 6583 \text{ \AA}$ ($>3\sigma$ significance)

110: extracted and fully reduced spectra from raw data to flux calibration

A far-away cluster

What do we observe?

A speculative picture of the situation

We ascribe lower metallicities in cluster star-forming galaxies to **the accretion of low-metallicity gas** from the surroundings

Dragging gas from motion and/or Accreting peripheral reservoirs

A prime discovery

“Warm” (10^4 °K) diffuse gas (**>100 kpc**) +
“Hot” (10^7 °K) extended atmosphere detected

A prime discovery

“Warm” (10^4 °K) diffuse gas (**>100 kpc**) +
“Hot” (10^7 °K) extended atmosphere detected

A prime discovery

Three hot questions in astrophysics

Giant Ly α nebulae

Early energy
injection in clusters

Galaxy activity in far-
away clusters

Putting observational constraints on all these issues with
a single process:

**“A giant Ly α nebula revealing early energy injection
in the hot intracluster medium”**

(Valentino et al. in prep.)

Preparing the future

Athena X-ray telescope (~2030) > Here at CEA!

So far so good

Articles:

- *"Metal deficiency in Cluster Star-Forming Galaxies at $z=2$ "* (**Valentino et al. 2015, Astrophysical Journal, 801, 132**)
- *"The gravitational collapse of a giant clump in a primordial galaxy"* (Zanella et al. 2015, Nature, 521, 54)
- *"Passive galaxies as tracers of cluster environments at $z\approx 2$ "* (Strazzullo et al. 2015, Astronomy & Astrophysics, 576, L6)
- *"Quenching of star formation in groups at $z\approx 1.8$ "* (Gobat et al. 2015, submitted)

Accepted **proposals:**

- ESO VLT/KMOS near-IR spectroscopy: 5+7.5 h (PI: Valentino)
- ESO VLT/MUSE optical spectroscopy: 1.5 h (PI: Valentino)
- IRAM/NOEMA sub-mm spectroscopy: 50 h (PI: Valentino)
- Several Col-ed proposals for time at major telescope facilities (Gemini, IRAM, ALMA, Subaru,...)

So far so good

October, 1st 2013: PhD start

Conferences and workshops:

- November, 17th-21st 2014: **Contributed talk** at the *“Third Workshop on Numerical and Observational Astrophysics: Linking the Local Universe to the Early One”* in Buenos Aires
- November, 25th-26th 2014: **Contributed talk** at the *“Journées Nationales PNCG 2014”* in Paris
- March, 23rd-27th 2015: **Contributed talk** at the *“Dissecting galaxies near and far: high resolution views of star formation and the ISM”* conference at ESO headquarters, Santiago de Chile
- April, 1st 2015: **Regular seminar** at the Universidad de Concepción
- June, 8th-12th 2015: **Contributed talk** at the *“IGM@50: is the intergalactic medium driving star formation?”* workshop at the Abbazia di Spineto
- June, 16th-19th 2015: **Contributed talk** at the *“Let’s group: the life cycle of galaxies in their favorite environment”* workshop at MPA, München

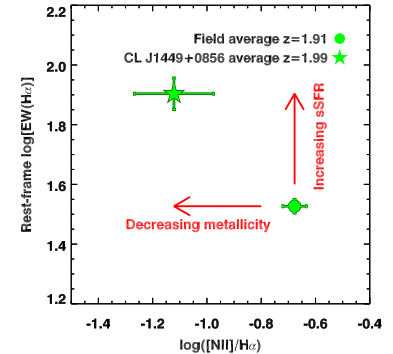

So far so good

And more!

- FMOS - Spectroscopic survey with the Subaru Telescope (Japan - France - Italy collaboration)
 - Hundreds of galaxies at $z \sim 1.5$
 - Still ongoing
 - First papers coming out now
- Redshift confirmation of a $z=2.2$ cluster (KMOS program)
- Line diagnostics and evolution of ISM conditions
- Tracing of star formation rate with $H\alpha$ in far-away clusters (KMOS program) and reversal of SFR-density relation

Summary

- Effect of nurture on gas properties in star-forming galaxies in a far-away cluster (Valentino et al. 2015, *Astrophysical Journal*, 801, 132)
- A giant Ly α nebula probing energy injection in far-away clusters (Valentino et al. in prep.)
- Long- and short-term projects

Back up

Nature vs nurture: a (still) interesting story to tell

- What about the high-redshift Universe ($z > 1.5-2$)?
- Estimating metallicities becomes challenging
- We approach an epoch where structures were **intrinsically different**

Contradictory results at high redshift (Kulas et al. 2013, Shimakawa et al. 2015 **vs** Kacprzak et al. 2015).

Gaining physical insight

We can convert $[\text{N II}]/\text{H}\alpha$ in **gas-phase oxygen abundance $12+\log(\text{O}/\text{H})$** by means of a proper calibration (e.g., Pettini & Pagel 2004, Steidel et al. 2014).

Known issues:

- Different calibrations give different absolute metallicities (Kewley & Ellison 2008)
- Standard calibrations are based on low-redshift galaxies
- Nitrogen-to-oxygen ratio is involved
- $[\text{N II}]/\text{H}\alpha$ is sensitive to the ionization parameter

Gaining physical insight

We can convert $[\text{N II}]/\text{H}\alpha$ in **gas-phase oxygen abundance $12+\log(\text{O}/\text{H})$** by means of a proper calibration (e.g., Pettini & Pagel 2004, Steidel et al. 2014).

Known issues:

- Different calibrations give different **absolute** metallicities (Kewley & Ellison 2008)
 - Standard calibrations are based on low-redshift galaxies
 - Nitrogen-to-oxygen ratio is involved
 - $[\text{N II}]/\text{H}\alpha$ is sensitive to the ionization parameter
- 
- We are measuring **relative** differences
 - We apply alternative line ratio metallicity indicators when possible ($O3N2$ and O_{32} , R_{23} for the cluster only). They are all in agreement with a low metal content in cluster star-forming galaxies.

Gaining physical insight

We can convert $[N II]/H\alpha$ in **gas-phase oxygen abundance $12+\log(O/H)$** by means of a proper calibration (e.g., Pettini & Pagel 2004, Steidel et al. 2014).

Known issues:

- Different calibrations give different absolute metallicities (Kewley & Ellison 2008)
- Standard calibrations are based on low-redshift galaxies
- Nitrogen-to-oxygen ratio is involved
- $[N II]/H\alpha$ is sensitive to the ionization parameter

Gaining physical insight

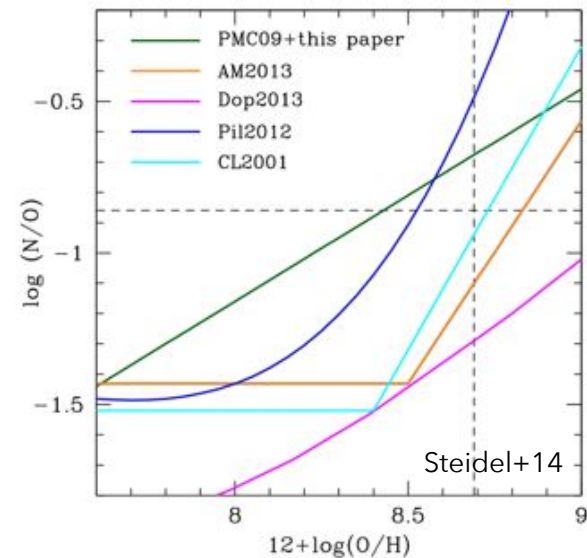

We can convert $[\text{N II}]/\text{H}\alpha$ in **gas-phase oxygen abundance $12+\log(\text{O}/\text{H})$** by means of a proper calibration (e.g., Pettini & Pagel 2004, Steidel et al. 2014).

Known issues:

- Different calibrations give different absolute metallicities (Kewley & Ellison 2008)
- Standard calibrations are based on low-redshift galaxies
- Nitrogen-to-oxygen ratio is involved
- $[\text{N II}]/\text{H}\alpha$ is sensitive to the ionization parameter

We estimated N/O from $[\text{N II}]/[\text{O II}]$ for the cluster only (Perez-Montero & Contini 2013):

$$\log(\text{N}/\text{O}) = -1.18 \pm 0.19$$

Gaining physical insight

We can convert $[\text{N II}]/\text{H}\alpha$ in **gas-phase oxygen abundance $12+\log(\text{O}/\text{H})$** by means of a proper calibration (e.g., Pettini & Pagel 2004, Steidel et al. 2014).

Known issues:

- Different calibrations give different absolute metallicities (Kewley & Ellison 2008)
- Standard calibrations are based on low-redshift galaxies
- Nitrogen-to-oxygen ratio is involved
- $[\text{N II}]/\text{H}\alpha$ is sensitive to the ionization parameter \mathcal{U}

For the cluster only, we could estimate \mathcal{U} from O_{32} , R_{23} following Kobulnicky & Kewley 2004:

$$\mathcal{U} \approx -2.61$$

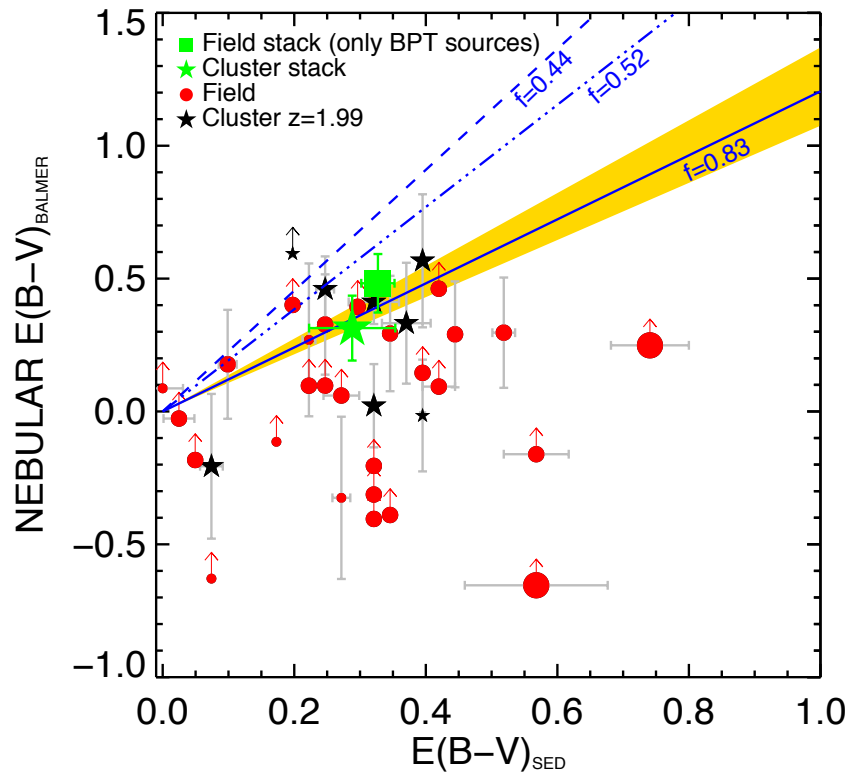

which is comparable with values measured in high redshift field galaxies

$$(-2.9 < \mathcal{U} < -2.0)$$

Possible selection effects

Nebular reddening

Fundamental Metallicity Relation

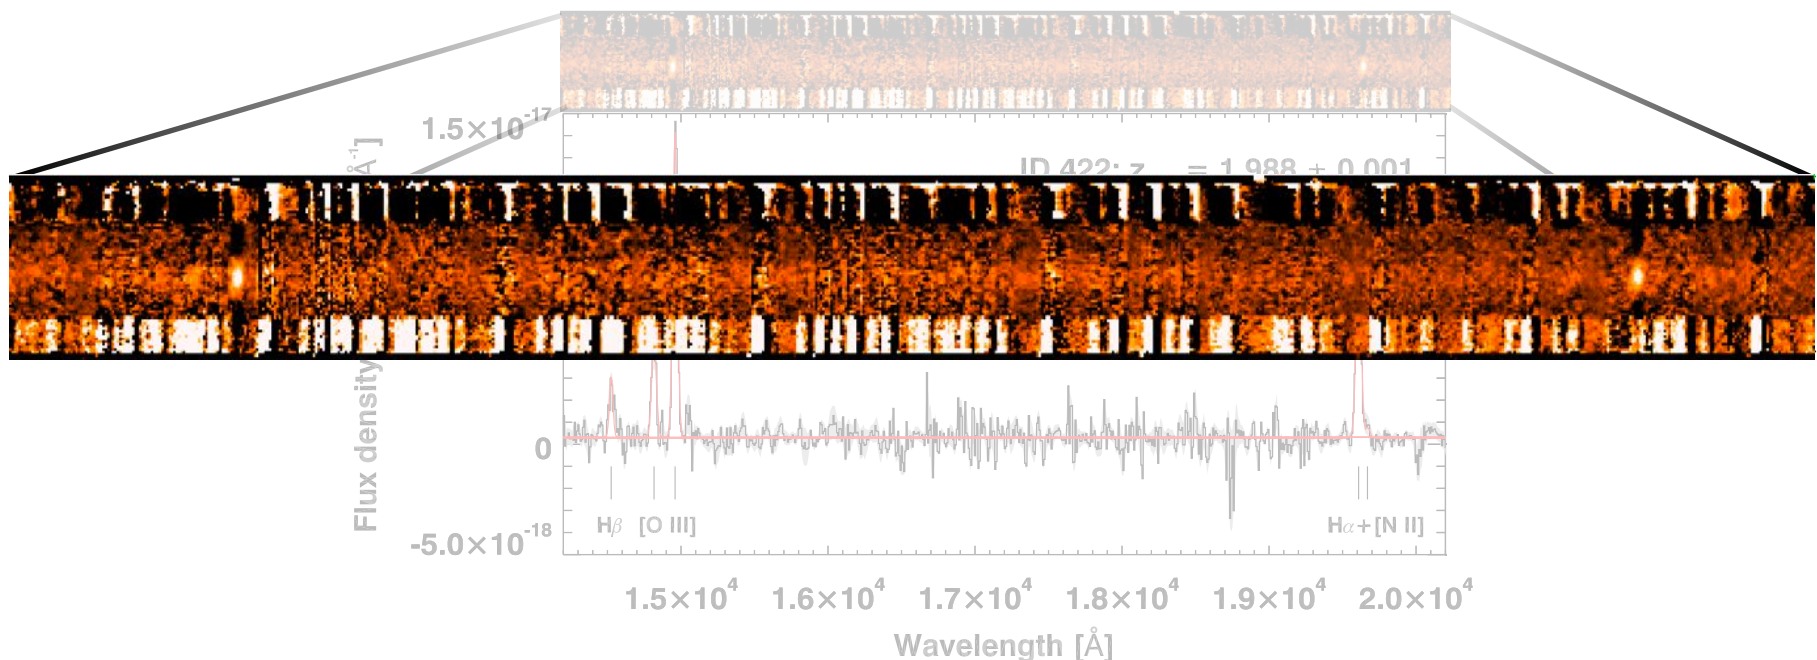

A speculative picture of the situation

Assembling/accreting
feature?

Near-infrared vision: MOIRCS follow-up

- Follow-up of 110 SFGs (including 10 cluster members) to primarily detect $H\alpha$ and $[N II]\lambda 6583\text{\AA}$.
- 71% success rate in detecting $H\alpha$ (3σ , minimum flux $\approx 1.4 \times 10^{-17}$ erg $\text{cm}^{-2} \text{s}^{-1}$), 20% in detecting $[N II]$. Upper limits on the remaining sample detected in $H\alpha$.
- $[O III]$ and $H\beta$ in the wavelength range according to redshift or from WFC3 G141.

Near-infrared vision: MOIRCS follow-up

- Follow-up of 110 SFGs (including 10 cluster members) to primarily detect H α and [N II] λ 6583Å.
- 71% success rate in detecting H α (3σ , minimum flux $\approx 1.4 \times 10^{-17}$ erg cm $^{-2}$ s $^{-1}$), 20% in detecting [N II]. Upper limits on the remaining sample detected in H α .
- [O III] and H β in the wavelength range according to redshift or from WFC3 G141.

Near-infrared vision: MOIRCS follow-up

AGN rejection combining X-ray emission, BPT (Baldwin et al. 1981) and $[\text{N II}]/\text{H}\alpha$ -EW($\text{H}\alpha$) diagrams (Cid Fernandes 2010).

A possible enhancement of sSFR

This picture could explain also the higher observed $\text{EW}(\text{H}\alpha)$ - **a proxy for the sSFR** - in cluster star-forming galaxies: **the accreted pristine gas would be triggering extra-star formation.**

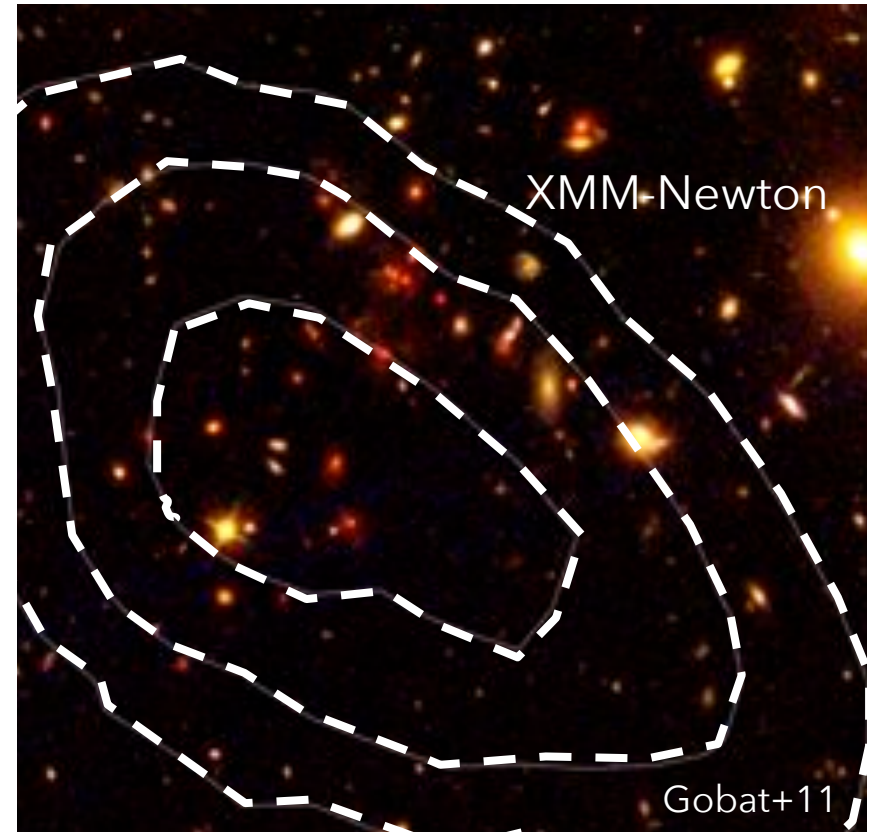

The remarkable case of CL J1449+0856 at $z=1.99$

A **relatively evolved cluster** (red, massive, quiescent galaxies in the core, extended X-ray emission), which hosts **a significant fraction of active galaxies** (Gobat et al. 2011, 2013, Strazzullo et al. 2013).

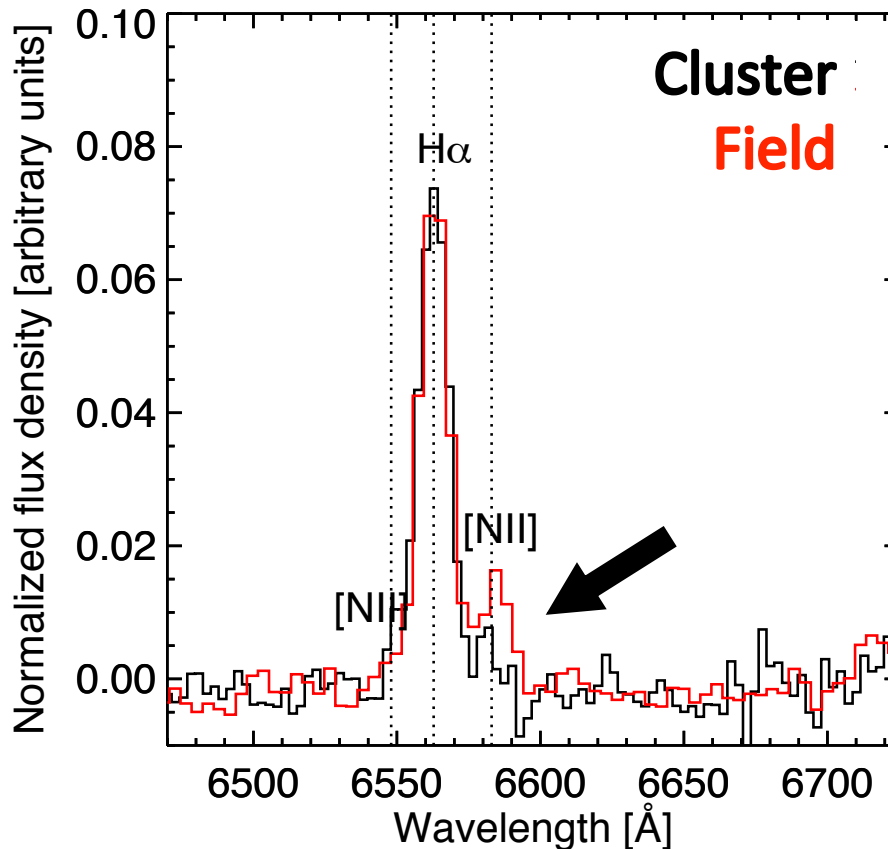

Extensively followed-up:

- 13-band photometry (**SED modelling**)
- HST/WFC3 slitless spectroscopy ([O II], $H\beta$, [O III] at $z\sim 2$)
- **Subaru/MOIRCS HK spectroscopy of star-forming galaxies**

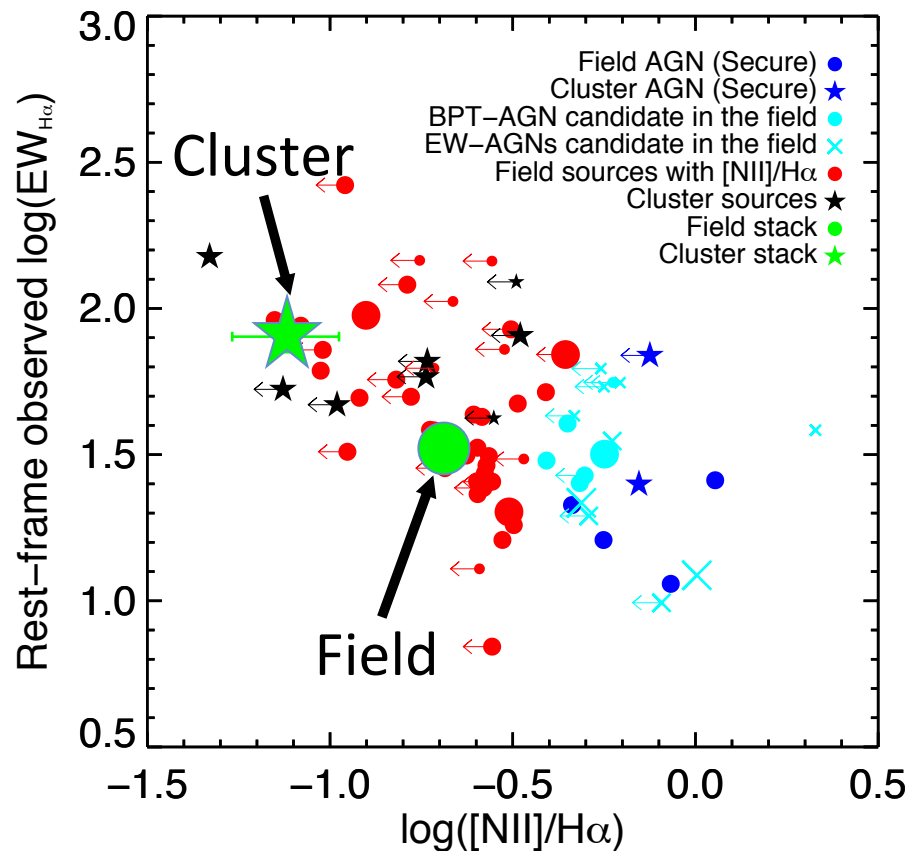

Observing an environmental signature

We detect a $\approx 4\sigma$ significant lower **[N II]/H α ratio in the cluster stacked sample** than in the mass-matched field sample (while [O III]/H β is compatible between the two).

Observing an environmental signature

We detect a $\approx 4.7\sigma$ significant higher observed $\text{EW}(\text{H}\alpha)$ in the **cluster stacked sample** than in the mass-matched field sample.

Gaining physical insight

We can convert $[\text{N II}]/\text{H}\alpha$ in **gas-phase oxygen abundance $12+\log(\text{O}/\text{H})$** by means of a proper calibration (e.g., Pettini & Pagel 2004, Steidel et al. 2014).

$$12+\log(\text{O}/\text{H}) = a + b \times \log([\text{N II}]/\text{H}\alpha)$$

Thus, star-forming galaxies in CL J1449+0856 are on average more metal poor than mass-matched field counterparts (by ≈ 0.09 - 0.25 dex, according to the calibration or indicator used)

Gaining physical insight

We can interpret the higher EW(H α) as **a proxy for the sSFR**.

$$\text{EW}(\text{H}\alpha) \approx \text{sSFR} \times 10^{0.4E(B-V)*k(\text{H}\alpha)*(1/f-1)}$$

Thus, star-forming galaxies in CL J1449+0856 have higher sSFRs (the significance of this result depends on the adopted reddening correction)

A speculative picture of the situation

We ascribe lower metallicities in cluster star-forming galaxies to **the accretion of pristine gas** from the surroundings, facilitated by the **"gravitational focusing effect"** (Martig & Bournaud 2007):
