

Spectroscopy of very heavy elements (II)

Ch. THEISEN
christophe.theisen@cea.fr

Outlook

- Interest and motivations
- Limits of stability : macroscopic aspects
- Decay modes
- Discovery of the heaviest elements
- Production
- Stability : microscopic aspects
- Decay spectroscopy
 - Technique, alpha decay, atomic effects, K-isomers
- Separators, spectrometers and focal plane devices
- Prompt spectroscopy
 - Recoil Decay Tagging
 - Gamma and electron spectroscopy
- Pushing the limits : facilities and devices

①

②

③

④

Limits of stability from liquid drop model

Magic numbers

	Z	N
W.S	114	184
HFB	126	184
RMF	120	172

Note 1 : Up to ^{208}Pb : proton and neutron magic numbers identical.

Note 2 : Models rely on extrapolations –parameters are adjusted on known cases

Experimental techniques

Prompt spectroscopy

Decay spectroscopy

Example 2 : alpha decay $^{255}\text{Lr} \rightarrow ^{251}\text{Md}$

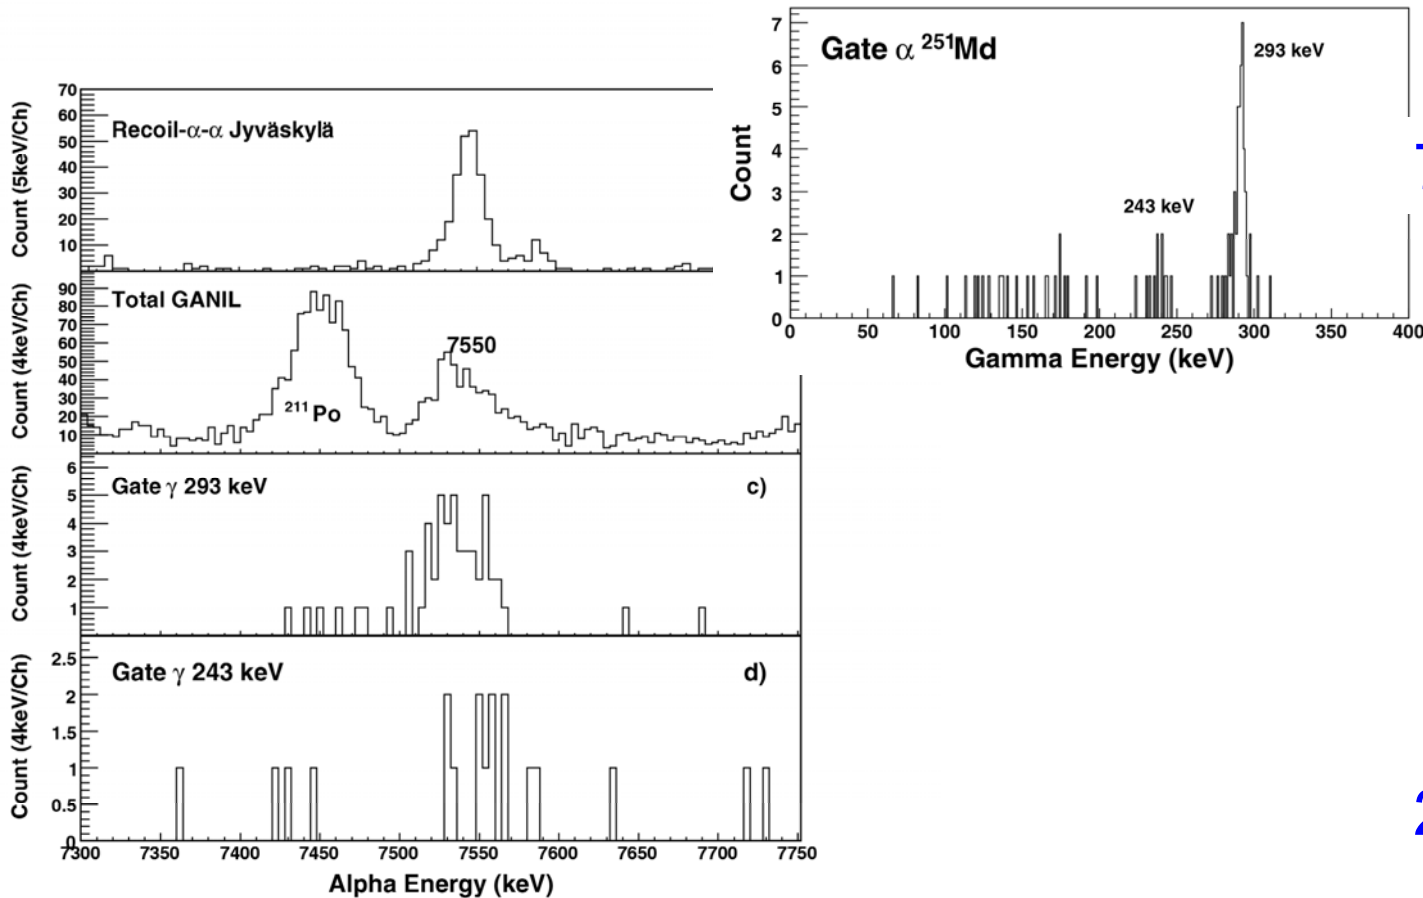

A. Chatillon et *al.*, EPJA 30 (2006) 397

Electromagnetic decay

Alpha-gamma and alpha-electron coincidences

Example :

^{251}Md

7550

293

243

50

^{247}Es

Electromagnetic decay

Electron conversion is high !

$$E_{\text{electron}} = E_{\text{transition}} - \text{Electron binding energy}$$

Conversion coefficient $\alpha = I(\text{electron})/I(\gamma)$

$\alpha \uparrow$ when $Z \uparrow$

$\alpha \uparrow$ when $E \downarrow$

$\alpha \uparrow$ when $\Delta I \uparrow$

- Example : 50 keV transition, $Z = 100$

	E1	E2	M1	M2
Total	$9.47 \cdot 10^{-1}$	$7.28 \cdot 10^2$	$8.78 \cdot 10^1$	$3.67 \cdot 10^3$
K	-	-	-	-
L	$7.03 \cdot 10^{-1}$	$5.16 \cdot 10^2$	$6.49 \cdot 10^1$	$2.59 \cdot 10^3$
M	$1.80 \cdot 10^{-1}$	$1.48 \cdot 10^2$	$1.61 \cdot 10^1$	$7.72 \cdot 10^2$

Atomic effects

X-Ray

Auger

Coster-Kronig

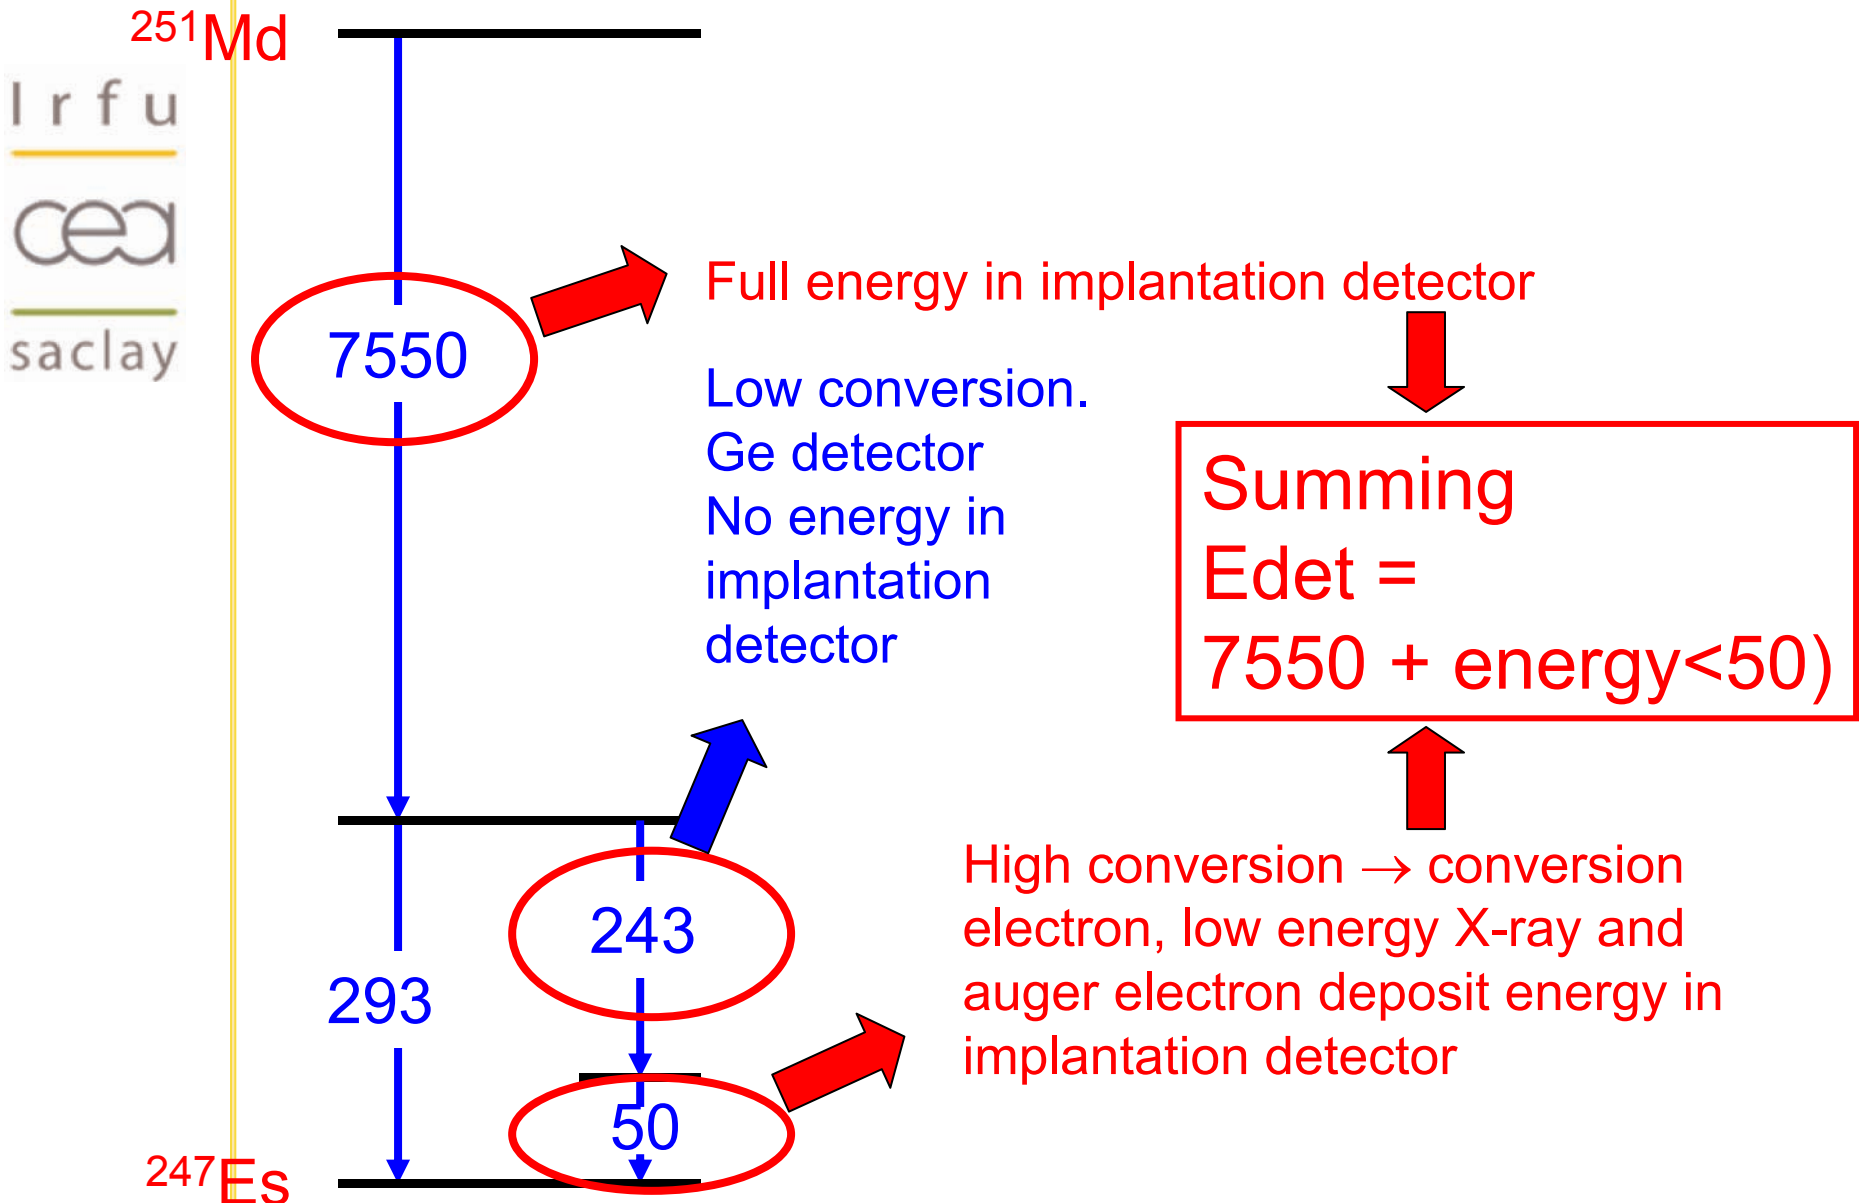

Example (Z=99 Conversion 50 keV M1)

- | | |
|--------------------------------------|------|
| 1 Conversion L_I | 23.2 |
| 2 Coster-Kronig $L_I-L_{III}M_{III}$ | 1.1 |
| 3 X $L_{III}-M_V$ | 16.0 |
| 4 X $M_{III}-N_I$ | 3.4 |
| 5 Auger $M_V-N_VN_{VII}$ | 2.9 |
| And so on... | |

Electron summing

Electron and X-ray summing

^{251}Md

l r f u

^{247}Es

Summing

Needs simulations to understand alpha spectra

Some alpha line do not correspond to a mother – daughter alpha transition, but result from the summing of alpha lines and atomic processes

(for details see Theisen, Lopez-Martens, Bonnelle NIM A 580 (2008) 230)

Alpha spectra have to be taken with care !

Alpha – gamma and electrons correlations

K-isomer

Example of Isomeric transition

K-isomer

- Degree of K forbidness $\nu = \Delta K - \lambda$
- Empirical rule :
$$F_W = \frac{T_{1/2}^\gamma(\text{experiment})}{T_{1/2}^\gamma(\text{Weisskopf})} \sim 100^\nu$$
- ie each degree of forbidness increases the lifetime by a factor of 100 compared to Weisskopf estimates

K-isomer

How to assign the configuration (proton or neutron) of a 2qp state (even even nucleus) ?

Comparison experiment - theory

General remarks

- Comparison of a given nucleus with theory is usually not very instructive. A more general view is needed e.g. comparison of isotopic or isotonic chain
- Accuracy of models not better than ~ 200 keV. Comparison of absolute energy like level ordering may be not instructive
- Collective vibrations or other degree of freedom like triaxiality may not be included in models (because of complexity)
- On the other side, trends, evolution in isotonic or isotopic chain is instructive.

Comparison with theory Es isotopes (I)

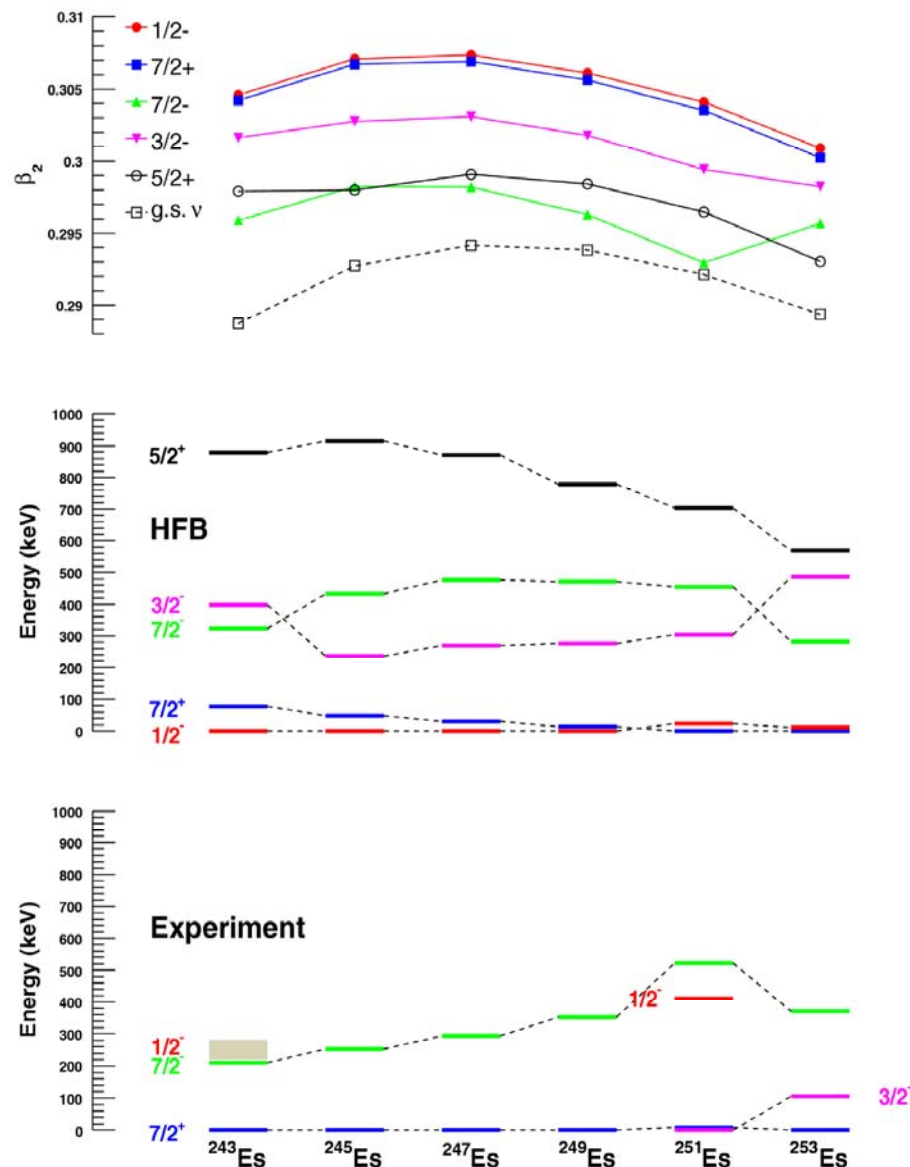

Trace separation of states
from 4 spherical shells:

$\pi[521]1/2^- (2f_{5/2})$

$\pi[514]7/2^- (1h_{9/2})$

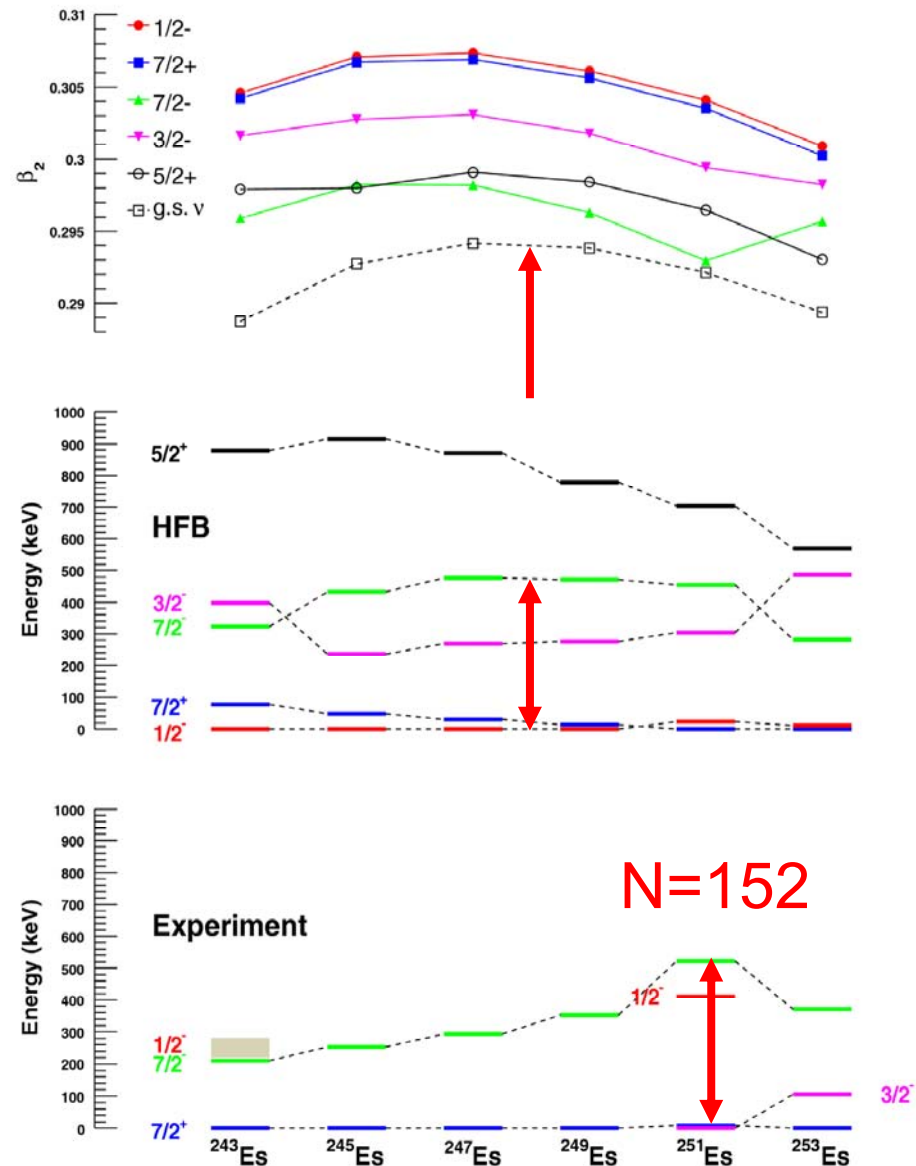

$\pi[633]7/2^+ (1i_{13/2})$

$\pi[521]3/2^- (2f_{7/2})$

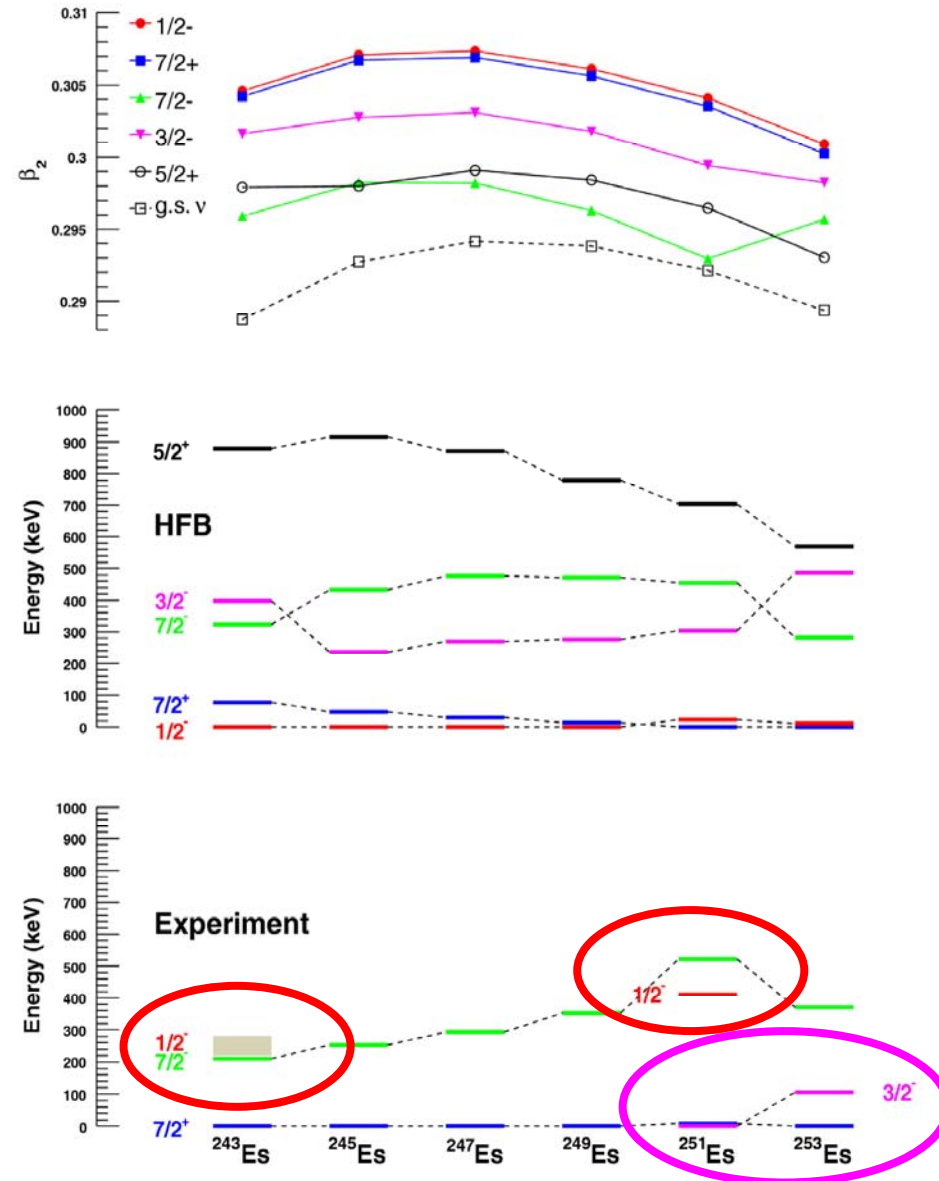

A. Chatillon et al., EPJA 30 (2006) 397

Comparison with theory Es isotopes (II)

Comparison with theory Es isotopes (III)

Comparison with theory Es isotopes (IV)

- Same conclusions for ^{251}Md and ^{255}Lr

- $N=152$ not well reproduced
- Spin-orbit splitting overestimated
- $Z=114$ gap slightly underestimated, but too small to establish a major shell closure

Separators, Spectrometers, Focal plane devices

- SHIP : GSI
- TASCA : GSI
- VASSILISSA + GABRIELLA : DUBNA
- DGFRS Dubna Gas Filled Recoil Separator : DUBNA
- LISE (FULIS) + BEST : GANIL
- RITU + GREAT : JYVASKYLA
- FMA : ARGONNE
- BGS : BERKELEY
- GARIS Gas Filled Recoil Ion Separator: RIKEN
- Gas Jet : JAERI

Beam rejection factor =

beam intensity / beam reaching the focal plane

Gas / Vacuum separator

Velocity filter

- Combination of electric and magnetic field

$$F_B = F_E \Rightarrow v = E/B$$

Example $^{22}\text{Ne} + ^{238}\text{U}$:

- $^{22}\text{Ne}(112 \text{ MeV})$ $v = 3.1 \text{ cm/ns}$,
- $^{260}\text{No} (9 \text{ MeV})$ $v = 0.26 \text{ cm/ns}$
- $^{238}\text{U} (34 \text{ MeV})$ $v = 0.53 \text{ cm/ns}$
- Examples ; SHIP, LISE ...

Gas / Vacuum separator

Gas separator = magnetic rigidity filter

$$F_B = qvB = mv^2/\rho$$

$$\text{gas : } \langle q \rangle = v/v_0 Z^{1/3} \Rightarrow B\rho \propto m/Z^{1/3}$$

Example $^{22}\text{Ne} + ^{238}\text{U}$:

$$^{22}\text{Ne} - B\rho = 0.76 \text{ T.m}$$

$$^{260}\text{No} - B\rho = 1.82 \text{ T.m}$$

$$^{238}\text{U} - B\rho = 1.89 \text{ T.m}$$

- High transmission
 - Target cooling
 - No mass selection
 - Ion slowing down
-
- Examples : RITU, BGS Berkeley, DGFRS Dubna, Tasca (GSI), GARIS (RIKEN)

Gas / Vacuum separator

Electric rigidity filter

$$F_E = qE$$

$$T = \frac{1}{2}mv^2$$

$$E_\rho = T/q$$

Example $^{22}\text{Ne} + ^{238}\text{U}$:

$$^{22}\text{Ne} - E_\rho = 11.7 \text{ MV}$$

$$^{260}\text{No} - E_\rho = 0.99 \text{ MV}$$

$$^{238}\text{U} - E_\rho = 1.93 \text{ MV}$$

Vassilissa

Focal plane devices

Need to combine

- Recoil energy and position
- Time of Flight or Energy loss for Recoils
- Alpha decay energy and position with best energy resolution
- Gamma detection with best efficiency and resolution
- Electron detection with best efficiency and resolution

Conversion is high !

Sacred + RITU

Prompt spectroscopy

Decay spectroscopy : low spin, low multiplicity cascades, mostly single particle states

Prompt spectroscopy : high spin because of fusion-evaporation reaction, high multiplicity, mostly collective states

Detection rate : dominated by fission; few 100 mb
beam intensity ~ 10 pA
event of interest \sim few / hour
→ very high sensitivity needed

A textbook example : ^{254}No

$^{208}\text{Pb}(^{48}\text{Ca}, 2n)^{254}\text{No}$ $\sigma \sim 2 \mu\text{b}$

Pioneer work performed (almost) at the same time at Argonne and Jyvaskyla

M. Leino *et al.* Eur. J. Phys A6 (1999) 63

P. Reiter *et al.* Phys. Rev. Lett 82 (1999) 509

Finding a needle in a haystack :

- $I_{\text{beam}} = 10 \text{ pA}$
- Ge counting rate $\simeq 100 \text{ kHz}$
- Good events $\simeq 10/\text{hour}$
- Sensitivity $\sim 10^{-8}$

²⁵⁴No Electron spectroscopy

P.A. Butler et al. Phys. Rev. Lett. 89 (2002) 202501

What to do with rotational bands ?

$$E(I) = E_0 + \frac{\hbar^2}{2\mathfrak{I}} I(I+1)$$

$$E_\gamma(I) = E(I+2) - E(I)$$

$$\Delta E_\gamma(I) = E_\gamma(I+2) - E_\gamma(I)$$

$$\hbar\omega = \frac{dE}{dI} \approx \frac{E_\gamma}{2}$$

$$\mathfrak{I}^{(2)} = \left(\frac{\partial^2 E}{\hbar^2 \partial I^2} \right)^{-1} = \hbar \frac{\partial I}{\partial \omega} \approx \frac{\Delta I^2}{\Delta E_\gamma}$$

What to do with rotational bands ?

Trends :

- Increase : pair alignment
- Alignment faster for N=150
As compared to N=152
- Odd-even effect difference :
blocking

saclay

Cohen, Plasil, Swiatecki. Ann. Phys. 82 (1974) 557

$$E_{L.D.}(Z,N,def,I) = E(Z,N,def) + \frac{\hbar^2 I^2}{2J(Z,N,def)}$$

Fission and angular momentum

- Transfermium nuclei should survive up to high spin $\sim 60 \hbar$
- Experimentally, rotation observed up to $\sim 20 \hbar$
- This is because experimentally, nuclei are produced using fusion-evaporation reaction with excitation energy (in addition to collective excitation). Fission probability is hence very large, which limits angular momentum (entry point).

Odd nuclei

$$E = \frac{\hbar^2}{2J} \{I(I+1)$$

$$- K^2$$

$$+ a\delta_{K,1/2}(-1)^{(I+1/2)}(I+1/2) \}$$

M1/E2 ratio

→ magnetic moment

→ configuration

B(M1)/B(E2) ratio

$$B(E2) = \frac{5}{16\pi} \langle I \ K \ 2 \ 0 \mid I-2 \ K \rangle^2 Q_0^2 (e^2 \text{ fm}^4)$$

$$B(M1) = \frac{3}{4\pi} K^2 (g_K - g_R)^2 \langle I \ K \ 1 \ 0 \mid I-1 \ K \rangle^2 (\mu_n^2)$$

$$B(M1; I \rightarrow I-1) = \frac{1}{2} |\langle + | iO(M1,y) + O(M1,z) | - \rangle|^2 \quad (\text{x: rotational axis})$$

with : $\checkmark O(M1) = \sqrt{\frac{3}{4\pi}} [(g_I^{\text{eff}} - g_R)I + (g_S^{\text{eff}} - g_R)s]$

MAY 1973

Isomeric States in ^{250}Fm and $^{254}\text{No}^\dagger$

Albert Ghiorso, Kari Eskola,* Pirkko Eskola,* and Matti Nurmia

Lawrence Berkeley Laboratory, University of California, Berkeley, California 94720

(Received 30 November 1972)

A preliminary report on the discovery of isomeric states in ^{250}Fm and ^{254}No was included in a recent article on α -emitting isotopes of element 104. The existence and assignments of the 1.8 ± 0.1 -sec isomer to ^{250}Fm and the 0.28 ± 0.04 -sec isomer to ^{254}No have now been confirmed by cross-bombardment techniques. Isomeric ratios based on measurements of collection efficiency of recoil atoms from the decay of isomeric states are given. An interpretation of the even-even isomers as high-spin two-quasiparticle states is discussed.

FIG. 1. A schematic diagram of the seven-detector-system. The cross section at right shows the arrangement of the two movable mother detectors and the two stationary daughter detectors.
